VISION

2026 has seen a huge influx of online betting and gambling. Gambling ruins lives, destroys families and ends with tragedies. People bet their hard-earned money on sports and world events. Gambling is an addiction and like all other addictions it cannot be quit “cold turkey”. My site is a free replacement for sportsbook sites. People can go on the site, bet with imaginary money and hopefully get the dopamine rush they were seeking, however this time no real money involved. Site will also feature resources for people who are looking to get help with their addiction.

OVERVIEW

User creates an account using their email and make a password (or passkey). Once in their home page, they can see their balance, current wages, past wages and on-going events that they can wage on. They can add money virtual money to their account which are given for free if they watch certain videos or click certain articles. Videos and articles are going to be on dangers of gambling. Once a certain even finishes they can see if their bet won or lost. If lost the amount waged is going to get deducted from their account and if otherwise vice versa. Here is AI generated diagram.

TECHNICAL OVERVIEW

Our environment will be hosted on FABRIC testbed. Users will be accessing our Kubernetes cloud environment through central API Gateway. There will be three distinct processing pods (services). Once service will continuously get live sports and odds data from some publicly available api (if there is any, if not I will be updating it daily manually). Second process is the wager pod where the user will be placing their bets. And third is the help resources such as links to videos and articles. For the backend I am going to use MongoDB that will store user data including their wagers.

SERVICES USED

- **FABRIC Testbed:** everything will be deployed here
- **Ansible:** used to configure OS, distribute ssh keys
- **RKE2:** Kubernetes engine
- **NGINX:** entry point to the cluster from internet
- **Node.js:** this will run the core microservices
- **React.js:** frontend
- **MongoDB:** backend

HOW TO BRING THIS VISION TO LIFE

This project has a lot of challenges for me. I had never worked with api before and never tried making a multi-pod service. However, I do have some ideas on how to achieve this. First of all, I will be using Ansible that will help me orchestrate the pods and save me some time. I will start with infrastructure first, setting up the ansible playbooks and making sure my deployments are working. My second phase is going to be backend. After that I will start adding the features I am envisioning and other fun stuff. I am expecting this project to take me about a month to finish and maybe another month to polish.
